Vegetation in Semi-Arid Regions

Figura : Bahia

- Consider the vegetation cover in water-poor regions.
- In this case, water is a *limiting factor*.
- quite different from tropical regions, where competition for water is irrelevant. One of the main limiting factor is light.
- We want to build a mathematical model (simple, please) — to describe the mutual relation between water in soil and biomass in semi-arid regions.

Image: Image:

Let us do it

(B)

Klausmeier Model

Figura : Colorado, USA

Figura : Kalahari, Namibia

- Water and vegetation, in a first approximation, entertain a relation similar to predador-prey dynamics.
- The presence of water is incremental for vegetation;
- Vegetation consumes water.
- But note that water does not originate from water.. It is an abiotic variable.
- The usual predator-prey dynamics does not apply.
- Consider two variables:
 - w,the amount of water in soil.
 - *u*, the vegetation biomass (proportional to the area with vegetation cover).

۲

$$\frac{dw}{dt} = a - bw - cu^2 w \qquad \qquad \frac{du}{dt} = -du + eu^2 w$$
Let us begin by defining two new variables, rescaled ones:

$$W = w \left[\frac{e}{\sqrt{b^3 c}} \right]$$

$$U = u \sqrt{bc}$$

$$T = tb$$
They are dimensionless.
Plug them into the equations and you will get....

$$\frac{dW}{dT} = A - W - WU^{2} \qquad \qquad \frac{dU}{dT} = WU^{2} - BU$$
• The algebraic equations has three roots:

$$U^{*} = 0$$

$$W^{*} = A$$
If $A > 2B$

$$U^{*} = \frac{2B}{A - \sqrt{A^{2} - 4B^{2}}}$$

$$W^{*} = \frac{A - \sqrt{A^{2} - 4B^{2}}}{2}$$

$$W^{*} = \frac{A + \sqrt{A^{2} - 4B^{2}}}{2}$$

3

イロト イポト イヨト イヨト

Interpretation

Our first conclusion:

- If A < 2B the only solution is $U^* = 0$ e $W^* = A$.
- This represents a bare state. A desert.
- The condition $A > 2B \Rightarrow a > \frac{2d\sqrt{bc}}{e}$ shows that there must be a minimum amount of precipitation to sustain vegetation.
- Moreover, the higher *e* the easier to have a state with vegetation.Recall that *e* represents the absorption rate. The higher, the better.
- On the other, the higher (b) and the death rate of the population, (d) easier it is to have a vegetationless solution.
- Seems reasonable!

VSAIFR

So, let A > 2B

- If A > 2B, we can have two fixed points.
- What about their stability?.
- The linear stability analysis results in:
 - ▶ The fixed point $U^* = 0$ and $W^* = A$ is always stable, even if $A \le 2B$.
 - The fixed point

$$U^* = \frac{2B}{A + \sqrt{A^2 - 4B^2}}, \quad W^* = \frac{A + \sqrt{A^2 - 4B^2}}{2}$$

is always unstable.

The fixed point

$$U^* = \frac{2B}{A - \sqrt{A^2 - 4B^2}}, W^* = \frac{A - \sqrt{A^2 - 4B^2}}{2}$$

is stable provided B < 2.

Roberto A. Kraenkel (IFT-UNESP)

São Paulo, Feb 2014 12 / 21

(日) (同) (三) (三)

C SAIRK

э

- So, if A > 2B, and B < 2, we have two stable fixed points, each of them with its basin of attraction.
- A pictorial view is as follows:

Figura : *B* is fixed, and we plot U^* (the biomass) in terms of *A*. The solution representing a desert ($U^* = 0$) and the solution corresponding to vegetation cover are both stable

э

(日) (同) (三) (三)

Hysteresis

- The existence of a region of bi-stability (A > 2B, B < 2), can take us to the following situation.
- Take a fixed *B*. Consider that *A* can change slowly.
- Let us begin in the bi-stability. And let A decrease. At a certain moment, A will cross the critical value A = 2B.
- At this time a sudden transition occurs, a jump, in which $U^* \rightarrow 0$. Desertification!!!.
- Suppose now that A begins again to increase slowly. As U* = 0 is stable, even with A > 2B we will continue in the "desertic" region, as at the moment of crossing back the critical point we were in its the basin of attraction..
- In summary: if we begin with a certain A, decrease it A < 2B and then come back to our initial value of A, the state of the system can transit from U^{*} ≠ 0 to U^{*} = 0.
- This is called Hysteresis.

э

(日) (同) (三) (三)

Hysteresis

Figura : *B* is fixed. *A* begins at a value A' with $U^* = U'$, decreases, crosses a critical point at A = 2B. It goes to , $U^* \to 0$. When we increase again *A*, even with A > 2B, we have $U^* = 0$.

Once the "desertic"state is attained it is \underline{not} sufficient to change the external conditions back (in our model, this is the rainfall) in order to get back a vegetation-cover state . Terrible!

C OMITIN

A B F A B F

Image: Image:

Glory and Misery of the Model

- Existence of sudden transitions can be understood rather simply. The same kind of phenomenon appears in other systems as well.
- The model is Simple.

A B F A B F

Image: Image:

Glory and Misery of the Model

Miserv

Figura : Desertification Region in China

Figura : Senegal, at the Sahel region, south to Sahara.

- The model is very simple
- The transition is towards a completely vegetationless state. Actual desertification processes allow for remnants of vegetation.
- The model predicts an infinite bi-stability region... We could think that enough rain could reverse desertification.
- There are indeed better models.

< A

More realistic models

• More realistic models give bifurcation diagrams like the one below.

Biomass in terms of the rainfall, in a static case.. The blue curve represents **two transition regions.** The one to the left implies a vegetation \rightarrow desert transition. To the right , a reversed transition.

More realist models

This diagram is similar to the preceding one, but U^* does not tend to zero.
