# Classical Lattice Models of Statistical Thermodynamics

Is the framework of Statistical Thermodynamics able to handle Phase Transitions ?

Brief History of Magnetic Phase Transition

▶ Pierre Curie, Paul Langevin and Pierre Weiss (1895-1910):

Boltzmann's framework for non-interacting micro-magnets.

• Wilhelm Lenz and Ernest Ising (1920):

Basic elements are dipoles which turn over among two positions,

$$Z = \sum_{\sigma_1 = \pm} \sum_{\sigma_2 = \pm} \cdots \sum_{\sigma_N = \pm} \exp[-\beta E(\sigma_1, \dots, \sigma_N)], \quad \beta = \frac{1}{k_B T}$$

► Werner Heisenberg and Paul Dirac (1928-1929):

$$E = \sum_{i,j} J_{ij}^{x} \sigma_{i}^{x} \sigma_{j}^{x} + J_{ij}^{y} \sigma_{i}^{y} \sigma_{j}^{y} + J_{ij}^{z} \sigma_{i}^{z} \sigma_{j}^{z}$$

#### ► Rudolf Pierls (1936):

2D Ising model display spontaneous magnetization for low temperatures prompting new interest.

Brief History of Magnetic Phase Transition

► Hendrick Kramers and Gregory Wannier (1941):

In 2D derived the Curie temperature and a combinatorial sums translated into a linear algebra problem,

 $Z = Tr[T^N]$ 

► Lars Onsager (1944):

2D Lenz-Ising model is exactly solvable since  $\Lambda_0 > \Lambda_1 > \dots$  was found,

$$Z = \Lambda_0^N \left[ 1 + (\frac{\Lambda_0}{\Lambda_1})^N + \dots \right]$$

The free-energy has no power law singularity as hypothesized,

 $f_s \sim |T - T_c|^2 \log(|T - T_c|)$ 

► Leo Kadanoff and Kenneth Wilson (1963-1975): At criticality we have scale invariance and the Curie critical point is

universal.

### Hamiltonian Limit

Thermal fluctuations (D+1) classical system  $\sim$  quantum effects D-spatial field theory,

Path Integral with space-time lattice,

$$K(x_a, t_a, x_b, t_b) = \langle x_a | \exp\left[-iH(t_b - t_a)\right] | x_b \rangle$$
  
= 
$$\int dx_{N-1} \dots dx_1 \langle x_b | T | x_{N-1} \rangle \langle x_{N-1} | T | x_{N-2} \rangle \dots \langle x_1 | T | x_a \rangle$$

with  $t_b - t_a = N\tau$  and  $T = \exp(-i\tau H)$ 

Amplitude with periodic boundary,

$$Z = \int K(x_0, N\tau, x_0, 0) dx_0 = Tr[T^N]$$

Free energy density Correlation function Correlation lenght Vaccum energy density Propagator Inverse mass gap

## Modeling Adsorption in Surfaces

• Greg Dash and Michael Bretz (1971):

Thin films of gases adsorbed on regular crystal surfaces: graphite has a hexagonal lattice.

The gas atoms slightly larger than a basic hexagon and two adjacent hexagons cannot both be occupied.

$$C \sim |T - T_c|^{-lpha}, \quad \alpha \cong 0.36$$

Tiling the Triangular Lattice

1

► Rodney Baxter (1980):

Consider a triangular lattice and place hexagonal tiles without overlapping

Let  $g(\boldsymbol{m},\boldsymbol{N})$  be the number of ways of placing  $\boldsymbol{m}$  hexagons on  $\boldsymbol{N}$  sites,

$$F(\mathfrak{z}) = \lim_{N \to \infty} \log [Z_N] / N, \quad Z_N = \sum_{m=0}^{N/3} \mathfrak{z}^m g(m, N)$$

#### Interaction Around Face Model

Spin  $\sigma = 0, 1$  and instead sites of adsorption one use face sites

 $\sigma_i \sigma_j = 0$  for all next-neighbors face variables

### The Ice Model

Introduced by Pauling in 1935 to explain the experimental fact that certain phase of Ice has a residual entropy.

The lattice sites are occupied by Oxygens **O** having four nearest neighbors Hydrogens **H** atoms:  $O \rightarrow O \rightarrow O$ . Here,  $A \rightarrow O \rightarrow O \rightarrow O$ .

#### The Vertex Representation

► To make water molecule H<sub>2</sub>O two Hydrogens are close to the central Oxygen and the other two are farther away.

- The statistical configuration sits on the edges and can be represented by an arrow whose tip points forwards the side where the Oxygen **O** is sited.
- The residual entropy can be computed,

$$S = k_B \log [\Lambda_0]$$

イロト 不得 トイヨト イヨト

### Brief History of Integrability

▶ Hans Bethe plane wave function (1931):

$$H = -\sum_{i,j} \sigma_i^{\mathsf{x}} \sigma_j^{\mathsf{x}} + \sigma_i^{\mathsf{y}} \sigma_j^{\mathsf{y}} + \Delta \sigma_i^{\mathsf{z}} \sigma_j^{\mathsf{z}}$$

• Elliott Lieb for  $\Delta = 1/2$  (1967):

Barry MacCoy and F. Wu (1968):

$$[T,H]=0,$$

provided the weights sit in the quadric,

$$\omega_1^2 + \omega_2^2 - \omega_3^2 - 2\Delta\omega_1\omega_2 = 0.$$

### Face Models Yang-Baxter

$$\sum_{d} W(a_{1}, a_{2}, d, c_{1}) W'(c_{1}, d, b_{2}, b_{1}) W''(d, a_{2}, c_{2}, b_{2})$$

$$= \sum_{d} W''(c_{1}, a_{1}, d, b_{1}) W'(a_{1}, a_{2}, c_{2}, d) W(d, c_{2}, b_{2}, b_{1})$$

#### **Onsager Star-Triangle Relation**

 $W_{h}(c,a)W_{v}^{'}(c,b)W_{h}^{''}(b,a) = \sum_{d}W_{v}^{''}(c,d)W_{h}^{'}(d,a)W_{v}(d,b)$ 

 $W_h''(a,b)W_v'(b,c)W_h(a,c) = \sum_d W_v(b,d)W_h'(a,d)W_v''(d,c)$
