Outline

1. The Hierarchy Problem
2. Supersymmetric Solution
3. Folded Supersymmetry
4. Conclusions
The hierarchy problem

The Standard Model Higgs potential is given by:

\[
V(H) = -\mu^2 H^\dagger H + \lambda (H^\dagger H)^2
\]  

Minimizing this potential we find:

Electroweak VEV \[ \Rightarrow \ v^2 = \frac{m^2}{2\lambda} \approx 246 \text{ GeV} \]  

Higgs boson mass \[ \Rightarrow \ m^2 = 2\mu^2 \approx 125 \text{ GeV} \]  

The physical value \( m_{phys}^2 \) is given by

\[
m_{phys}^2 = m^2 + \delta m^2
\]  

Fine tuning: \[ \frac{m_{phys}^2}{\delta m^2} \times 100\% \]
The hierarchy problem

Assume the Standard Model is valid up to an energy $\Lambda$ (cutoff).

Figure 1: One loop contributions to the Higgs mass parameter due to (a) top quark, (b) gauge boson and (c) Higgs self-interactions.

\[
\begin{align*}
(a) & \quad - \frac{3}{8\pi^2} y_t^2 \Lambda^2 \sim -(2000\text{GeV})^2, \\
(b) & \quad \frac{1}{16\pi^2} g_2^2 \Lambda^2 \sim (700\text{GeV})^2 \\
(c) & \quad \frac{1}{16\pi^2} \lambda \Lambda^2 \sim (500\text{GeV})^2
\end{align*}
\]

for $\Lambda = 10$ TeV.

\[ m_{\text{phy}}^2 \approx m_{\text{bare}}^2 - (100 - 10 - 5)(200\text{GeV})^2 \quad (6) \]

Fine tuning of 1%.

Figure 2: Chiral supermultiplet fields in the MSSM with corresponding transformations under the gauge group. The index $I$ runs from 1 to 3 and denotes each of the three families of particles.
Cancellation of the top loop contribution in the MSSM

- Superpotential:
  \[ W_{\text{MSSM}} = y_{IJ}^U U_I Q_J \cdot H_U - y_{IJ}^D D_I Q_J \cdot H_D - y_{IJ}^E E_I L_J \cdot H_D + \mu H_U \cdot H_D. \tag{7} \]

  \[ \Rightarrow \mathcal{L}_{\text{MSSM}} \supset -y_t \left[ t_R^C t_L h_U^0 + h.c. \right] - y_t^2 |\tilde{t}_L h_U^0|^2 - y_t^2 |\tilde{t}_R h_U^0|^2 \tag{8} \]

- Stops have the same quantum numbers as the top particle.
- Coupling parameters are related by supersymmetry.
Colored top partners are easier to produce at the LHC. However, none of them were detected, so far.

In theories with “Neutral Naturalness”, the top partners are uncolored and their cross sections are suppressed.
Cancellation of quadratic divergences in Little Higgs and twin Higgs models

- **Little Higgs**: Top partners are fermions with the same quantum numbers as the top quark. Interactions parameters are related by a global symmetry.
  

- **Twin Higgs**: Top partners are also fermions but they do not necessarily have the same quantum numbers. Interaction parameters are related by a discrete symmetry.
  
Question:
Is it possible to construct theories where the quadratic divergence from the top loop is canceled by diagrams similar to the supersymmetric case where the top partners are neutral under $SM$ color?
Question: Is it possible to construct theories where the quadratic divergence from the top loop is canceled by diagrams similar to the supersymmetric case where the top partners are neutral under $SM$ color?

Answer: Yes
**Question:**
Is it possible to construct theories where the quadratic divergence from the top loop is canceled by diagrams similar to the supersymmetric case where the top partners are neutral under SM color?

**Answer:** Yes

**FOLDED SUPERSYMMETRY**
Question: Is it possible to construct theories where the quadratic divergence from the top loop is canceled by diagrams similar to the supersymmetric case where the top partners are neutral under SM color?

Answer: Yes

FOLDED SUPERSYMMETRY

1. Supersymmetrize.
2. Enlarge the symmetry in order for the theory to enjoy bifold protection.
3. Project out the states odd under the combined $\mathbb{Z}_2 \Gamma \times \mathbb{Z}_2 R$ discrete symmetry.

 Carlos Bautista
 Folded Supersymmetry as a Neutral Natural solution to the Hierarchy Problem of the Standard Model 23/06 10 / 14
Toy Model

1. Supersymmetrize.
2. Enlarge the symmetry in order for the theory to enjoy bifold protection.
3. Project out the states odd under the combined $Z_{2\Gamma} \times Z_{2R}$ discrete symmetry.
Application to the Standard Model Yukawa term

- In the SM, the top Yukawa terms are:
  \[ \mathcal{L}_{SM} \supset -y_t \left( \bar{q}_3 \tilde{H} u_3 + \bar{u}_3 \tilde{H}^\dagger q_3 \right). \tag{9} \]

- Supersymmetrization implies
  \[ \mathcal{W}_{MSSM} \supset y_t Q_3^{\alpha} \cdot H_U U_3^{\alpha}, \tag{10} \]
  where fields transform as
  \[ Q_3(3,2), \quad H_U(1,2), \quad U_3(\bar{3},1). \tag{11} \]
  under the \( SU(3)_C \times SU(2)_L \) local group.

- The supersymmetric Lagrangian contains
  \[ \mathcal{L} \supset -y_t \left[ \bar{u}_3^{\alpha} q_3^{\alpha} \cdot \tilde{h}_u + \bar{q}_3^{\alpha} \cdot \tilde{h}_u u_3^{\alpha} + h_u \cdot q_3^{\alpha} u_3^{\alpha} + \text{h.c.} \right] \]
  \[ - y_t^2 \left[ |\bar{q}_3 \cdot h_u|^2 + |h_u|^2 |\bar{u}_3|^2 + |q_3|^2 |\bar{u}_3|^2 \right]. \tag{12} \]
We will enlarge the symmetry from $SU(3) \times SU(2)$ to $SU(6) \times SU(2)$. The superpotential will contain

$$W_{MSSM} \supset y_t Q_3^\alpha \cdot H_U U_3^\alpha,$$

but now the fields transform as

$$Q_3(6,2), \quad H_U(1,2), \quad U_3(\bar{6},1).$$

under the $SU(6) \times SU(2)$ local group.

- $Q_3$ contains, in addition to the three color states of the SM, three new states charged under $SU(2)_L$ and $U(1)_Y$ but not under $SU(3)_C$ of the SM.

- $U_3$ contains, in addition to the 3 color states of the SM, three exotic states charged under $U(1)_Y$ but not under SM color.

These new fields are called Folded partners (or F-partners, for short) of the corresponding MSSM fields.
Under the combined symmetry $Z_2\Gamma \times Z_2R$, fields transform as

\[
\begin{align*}
\tilde{q}_3 &= \left( \begin{array}{c} \tilde{q}_A(-) \\ \tilde{q}_B(+) \end{array} \right), & q_3 &= \left( \begin{array}{c} q_A(+) \\ q_B(-) \end{array} \right), \\
\tilde{u}_3 &= \left( \begin{array}{c} \tilde{u}_A(-) \\ \tilde{u}_B(+) \end{array} \right), & u_3 &= \left( \begin{array}{c} u_A(+) \\ u_B(-) \end{array} \right),
\end{align*}
\]

(15) (16)

Orbifolding out the odd states:

\[
\mathcal{L} \supset -y_t \left[ h_u \cdot q_A^{\alpha} u_A^{\alpha} + \text{h.c.} \right] - y_t^2 \left[ |\tilde{q}_B \cdot h_u|^2 + |h_u|^2 |\tilde{u}_B|^2 + |\tilde{q}_B|^2 |\tilde{u}_B|^2 \right]
\]

(18)
Conclusions

- One loop divergent contributions to the mass of \( h_u \) cancel out. Furthermore, we note that the fermionic loop with fields charged under \( SU(3) \) SM color is canceling out with bosonic loops not charged under \( SU(3) \) SM color but under another \( SU(3) \) hidden color group.
- Since the fields \( \tilde{q}_B \) and \( \tilde{u}_B \) do not couple to fermionic fields, quadratically divergent contribution to their masses will not cancel. Then, radiative stability of the mass of \( h_u \) is not guaranteed to orders higher than one.
- A UV completion is needed in order to set the values of the parameters at high scale. This can be done by embedding the fields in a 5 dimensional space-time and applying suitable boundary conditions.
