NRGR for the two-body problem: an overview

Riccardo Sturani

Instituto de Física Teórica UNESP
International Center for Theoretical Physics - South American Institute for Fundamental Research

riccardo.sturani@unesp.br

14/8/23 – Principia Institute – QCD meets Gravity in Brasil
Fundamental aspects of the EFT formalism

NRGR & PN approximation to GR: Small expansion parameter $\nu$, related to metric perturbation $\nu^2 \sim \frac{GM}{r}$

Near zone, $D \sim r$

Far zone, $D \gg \lambda = r/\nu$

Describe conservative dynamics

EFT framework pioneered by W. Goldberger & I. Rothstein, hep-th/0409156

for spin R. Porto, gr-qc/0511061 (no spin in this talk)

Inspired by NRQCD, see e.g. Manohar & Stewart hep-ph/0605001

and then integrated over the full phase space

Only potential and radiation gravitons exchanged in classical processes: theory in terms of world lines selects diagrams that do not send source off-shell

Potential graviton → small change in energy wrt momentum, dominate classically

Ex. of classical/quantum connected diagrams
Near zone conservative dynamics

The potential $V$ (via Feynman Green function):

\[
V \propto \int d\omega d^3k \frac{e^{-i\omega t_{12} + i\vec{k} \cdot (\vec{x}_1(t_1) - \vec{x}_2(t_2))}}{k^2 - \omega^2 - i\epsilon} = \int d\omega d^3k \frac{e^{-i\omega t_{12} + i\vec{k} \cdot \vec{x}_{12}}}{k^2} \left(1 + \frac{\omega^2}{k^2} + \ldots\right)
\]

\[
= \delta(t_1 - t_2) \int d^3k \frac{e^{i\vec{k} \cdot \vec{x}_{12}}}{k^2} \left(1 + \frac{\partial t_1 \partial t_2}{k^2} + \ldots\right)
\]

\[
= \int d^3k \frac{e^{i\vec{k} \cdot \vec{x}_{12}}}{k^2} \left(1 - \frac{\vec{k} \cdot \vec{v}_1}{k^2} + \ldots + \frac{\vec{k} \cdot \frac{d^{n-1}v_1}{dt^{n-1}} \vec{k} \cdot \frac{d^{n-1}v_2}{dt^{n-1}}}{k^{2n}}\right)
\]

- Instantaneous interaction + trajectory derivatives
- Near zone amplitude integrands clearly bad behaved for $k \to 0$ (though no IR divs at $O(G)$). Integrated all the way to $k \to 0$!
  Fix: add the contribution of far-zone, for demonstration see e.g.

  Manohar & Stewart hep-ph/0605001, Jantzen 1111.2589, Blumlein+ 1902.11180,
  Foffa & RS 2103.03190
NR zone trades knowledge over the full trajectory with knowledge of all derivatives of the trajectory at equal time (PN approximation)

\[
+ \dot{v} \sim \frac{v^2}{r} \\
+ \ddot{v} \sim \frac{v^3}{r^2} \\
+ \ldots
\]
Scale separation → Near + Far

The full \( I \), Near, Far zone integral are

\[
I \equiv e^{-i\omega t} \frac{1}{k^2 - \omega^2},
\]

\[
N \equiv e^{-i\omega t} \sum_{m\geq 0} \left( \frac{\omega^2}{k^2} \right)^m \frac{1}{k^2 - \omega^2},
\]

\[
F \equiv e^{-i\omega t} \sum_{n\geq 0} \frac{(i\mathbf{k} \cdot \mathbf{x})^n}{n!} \left( \frac{\omega^2}{k^2} \right)^m \frac{1}{k^2 - \omega^2},
\]

Decomposing

\[
\int_k I = \int_k F + \int_k N + \int_{k < \bar{k}} \left( I - F - N \right) + \int_{k > \bar{k}} \left( I - N - F \right)
\]

\[
= \int_k F + \int_k N + \int_{k < \bar{k}} N + \int_{k > \bar{k}} F
\]

\[
= \int_k F + \int_k N + \int_{k < \bar{k}} \sum_{n,m} \frac{(i\mathbf{k} \cdot \mathbf{x})^n}{n!} \left( \frac{\omega^2}{k^2} \right)^m
\]

\[=0 \text{ in dim. reg}.
\]
Matching: Multipoles in terms of two-body variables

Expanding in powers of the external momentum one obtains the coupling between long wavelength and multipole moments.
(IR) Divergences in the Near zone

IR divergences due to splitting into Near and Far

In the full theory:

\[
V \supset \int dt_{1,2,2'} d^4 k e^{ik_\mu(x_1^\mu(t_1) - x_2^\mu(t_2))} \frac{p^\alpha p^\beta}{p^2} \int d^4 q \frac{e^{iq_\mu(x_2(t_2) - x_2(t'_2))}}{(k - q)^2 q^2} \Delta(k^\mu(x_2(t_2) - x_2(t'_2)))
\]

after near/far breaking:

\[
\int dt d\omega d^3 k e^{-i\omega t_{12}} e^{i\vec{k} \cdot \vec{x}_{12}} k^i k^j \left\{ 1 + \ldots + \frac{1}{|k|^4} \left[ \ldots \vec{k} \cdot \vec{a}_1 \vec{k} \cdot \vec{a}_2 \right] + \frac{1}{|k|^6} \left[ \ldots \vec{k} \cdot \vec{a}_1 \vec{k} \cdot \vec{a}_2 \right] \right\}
\]
Compensating divergences Near - Far

- Near IR/Far UV

\[ V \supset GM Q_{ij} \left( \frac{1}{\epsilon_{UV}} + \log(\mu \omega) \right) + GMm_1m_2r^2 a_1^{i} a_2^{i} \left( \frac{1}{\epsilon_{IR}} + \log(\mu r) \right) \]

Theory at short and large distances have compensating spurious divergences, finite terms derived straightforwardly (Manohar & Stewart, Jantzen)

- Near zone UV divergences canceled by local counterterms:

\[ G^2 m_a^3 \int d\tau (a^\mu \dot{v}_\mu + R_{\mu\nu} v^\mu v^\nu) \]

Foffa, RS, Porto, Rothstein 1903.05118

- No far zone IR divergences

- From far zone alone → leading UV logs in the Energy function at all orders via Renormalization group flow (see later in this talk)

Goldberger, Ross, Rothstein 0912.4254, 1211.6095, Blanchet, Foffa, Larrouturou, RS 1912.12359
Diagrams proliferations

E.g. at $5PN$: $G^3$, $G^2 72$, $G^3 2702$, $G^4 41676$, $G^5 116498$, $G^6 27582$

at $6PN$: $G^3$, $G^2 24$, $G^3 485$, $G^4 5553$ (symmetrised)

Blumlein, Maier, Marquard, Schäfer 2010.13672, 2101.08630

For PN expansion it is useful to distinguish gravity polarizations, e.g. $G^2_N$

22 topologies

23 Feynman diagrams at 4PN ($G^2 v^3$)

$\sim h_{00} \rightarrow v^0$; $\sim h_{0i} \rightarrow v^i$; $\sim h_{ij} \rightarrow v^i v^j$;

However only 1 of the two topologies is intrinsically $G^2_N$
EFT and amplitude: tale of a happy marriage

The other obstruction to scalability of the NRGR PN calculation program (common problem with other framework) is the computation of master integrals.

E.g. in the static 4PN sector (i.e. $G_N^5$) one meets

$$= -i (8\pi G_N)^5 \left( \frac{(d-2)}{(d-1)} m_1 m_2 \right)^3$$

in terms of 4-loop self-energy diagrams in gauge theory.
Reduction in terms of master integrals

No new master integrals at 5PN, 4PN ones did it all

\[ \frac{e^{2\varepsilon \gamma_E}}{s^{2-2\varepsilon} (4\pi)^{4+2\varepsilon}} \left\{ \frac{1}{2\varepsilon^2} - \frac{1}{2\varepsilon} - 4 + \frac{\pi^2}{24} ight\} 

- \varepsilon \left[ 9 - \pi^2 \left( \frac{13}{8} - \log 2 \right) - \frac{77}{6} \zeta_3 \right] + O(\varepsilon^2) \]

Numerical result obtained via Summertime by Lee & Mingulov
analytic result via PSLQ algorithm, fitting transcendentals to numerical result

Confirmed up to \( O(\varepsilon^0) \) by Damour, Jaranowski '18

Foffa, Mastrolia, RS, Sturm '17

Foggia, Mastrolia, RS, Sturm '17
Including radiative modes

In Far zone self-energy diagrams, careful is needed when using radiative modes.

Two oriented propagators treatable with standard Feynman Green functions (in-out)

Real part

\[ E: \quad \text{Self-E} \sim (\ddot{Q})(\ddot{Q}) \sim 0 \]

\[ \text{tail}^1 \sim GM(\ddot{Q})^2 \log x^4 \log x \]

\[ \text{tail}^2 \sim (GM)^2(\ddot{Q})(\ddot{Q})x^{11/2} \]

Imaginary part

\[ \frac{dE}{dt}: \quad \text{LO flux} \sim \pi x^{3/2} \]

\[ \text{tail}^1 \sim \pi x^{3/2} \]

\[ \text{tail}^2 \sim x^3 \log(x) \]

\[ \tilde{G}_F = \frac{1}{2}(\tilde{G}_A^2 + \tilde{G}_R^2) - \tilde{\Delta}_+\tilde{\Delta}_- + i(\tilde{G}_R + \tilde{G}_A)(\tilde{\Delta}_+ + \tilde{\Delta}_-) \]

Other insertions possible:

\[ M \rightarrow Q, L \quad \text{When more than two rad. props in-in needed} \]

(see talks in the next weeks by Almeida and Foffa)
NRGR is an efficient method for computations from first-principle, automatically kills quantum contributions.

Divergences (both UV and IR) well understood (indeed highly constrained hence helpful for sanity checks).

Higher order $\rightarrow$ new master integrals, same problem for any perturbative method (PN, PM...) 

Diagram proliferation: necessary smart ideas and/or efficient codes.

Conservative + Averaged flux from in-out formalism for up to 2 radiative modes, for more radiative modes WIP.
Double copy for EFT

Master integrals have to do with denominators, however numerators can be simplified too by writing $A_{GR} = A_{YM}^2$

Bern, Carrasco, Johansson PRD ’08

On-shell three vertices can be mapped:

```
gauge theory  \rightarrow  gravity theory

\text{color factors}  \rightarrow  \text{kinematic numerator}
```

Interactions at high loop $\rightarrow$ lengthy expressions, double copy?

See e.g. Goldberger+ ’18, Chen ’18, Almeida+ ’20
Double Copy of Far amplitudes

also doubling of world-line vertex \( d_i F_{0i} \rightarrow I_{ij} E_{ij}, \mu_i F_{ij} \rightarrow J_{ij} B_{ij} \)

Verified for both electric and magnetic multipoles at NLO in \( G_N \)

Goldberger, Ridgway ’18, Shen ’18, Almeida+ ’20

Yet to be verified derivation how YM → GR mapping propagates from “microscopic physics” to multipoles
Double Copy Far continued

Electric Self-Energy

1. LO: \( l_{ij_1...i_r}(\omega)l_{ij_1...i_r}(-\omega) \frac{k_{i_1}...k_{i_r} k_{k_1}...k_{k_r}}{k^2 - \omega^2} (\omega^2 \delta_{ik} - k_i k_k) (\omega^2 \delta_{jl} - k_j k_l) \)

2. NLO: \( l_{ij_1...i_r}(\omega)l_{ij_1...i_r}(-\omega) \frac{k_{i_1}...k_{i_r} k_{k_1}...k_{k_r}}{(k^2 - \omega^2)((k+q)^2 - \omega^2)q^2} \omega^2 \)
\( \times (\omega^2 \delta_{ik} - (k + q)_i k_k + q_i q_k) (\omega^2 \delta_{jl} - (k + q)_j q_l + q_j q_l) \)

- analogously for the magnetic self-Energy at LO and NLO

Gravity+dilaton+anti-symmetric tensor amplitude matches gauge\(^2\)
Factorizable diagrams at $G^5$ 5PN

At $G^5 v^2$:

\[
\left( \begin{array}{ccc} 
\text{Diagram 1} \\
\text{Diagram 2} \\
\text{Diagram 3} \\
\text{Diagram 4} \\
\text{Diagram 5} 
\end{array} \right)^5 + \left( \begin{array}{ccc} 
\text{Diagram 6} \\
\text{Diagram 7} \\
\text{Diagram 8} \\
\text{Diagram 9} \\
\text{Diagram 10} 
\end{array} \right) \times \left( \begin{array}{ccc} 
\text{Diagram 11} \\
\text{Diagram 12} \\
\text{Diagram 13} \\
\text{Diagram 14} \\
\text{Diagram 15} 
\end{array} \right)^3
\]

\[+ (31 G^3_N \text{prime dgrs}) \times \left( \begin{array}{ccc} 
\text{Diagram 16} \\
\text{Diagram 17} \\
\text{Diagram 18} \\
\text{Diagram 19} \\
\text{Diagram 20} 
\end{array} \right) + \left( \begin{array}{ccc} 
\text{Diagram 21} \\
\text{Diagram 22} \\
\text{Diagram 23} \\
\text{Diagram 24} \\
\text{Diagram 25} 
\end{array} \right)^2 \]

\[+ (171 G^4_N v^2 \text{prime dgrs}) \times \left( \begin{array}{ccc} 
\text{Diagram 26} \\
\text{Diagram 27} \\
\text{Diagram 28} \\
\text{Diagram 29} \\
\text{Diagram 30} 
\end{array} \right)^2 \]

They amount to 1232 out of 1907 $G^5 v^2$ diagrams

Foffa, RS. W. J. Torres Bobadilla, 2010.14550
All leading logs in $E_{\text{circ}}(x)$

$$E_{\text{circ}} = -\frac{M \nu}{2} x \left(1 + \frac{16 \nu x^2}{15 \beta_i} \left(\left(1 + 24 \beta_i x^3 \log x\right) x^{4 \beta_i x^3} - 1\right)\right) \quad \beta_i = -\frac{214}{105}$$

- In PN approximation Log terms arise from tail processes at 4PN order, non-local (but causal) effective term in conservative dynamics ($x \sim \nu^2 \sim Gm/r \equiv \gamma$):

  $$\mathcal{L} = \frac{M \nu}{2} v^2 + \ldots + \frac{2 G^2 M}{5} Q_{ij}(t) \int d\tau \log(\tau) Q_{ij}(t - \tau) \ldots$$

  $$\rightarrow E_{\text{circ}} = -\frac{M \nu x}{2} \left(1 + \ldots + \frac{448}{15} \nu x^5 \log x + \ldots\right)$$

  which turns local on circular orbits

- Expansion in $GM\omega = \frac{GM}{r} \times r\omega \sim \nu^3$:

LO tail: Blanchet, Damour PRD ('88)
Leading Logs at all orders

Real part $E$:

- Self-$E \sim (\bar{Q})(\bar{Q}) \sim 0$
- $\text{tail}^1 \sim GM(Q)^2 \log t \sim (GM)^2(Q)(\bar{Q}) x^4 \log x$
- $\text{tail}^2 \sim (GM)^2(Q)(\bar{Q}) \log x \sim (GM)^2(Q)(\bar{Q}) x^{11/2}$
- $\text{tail}^3 \sim (GM)^3(\log + \log^2) \times (\bar{Q})(\bar{Q}) x^7(\log x + \log^2 x)$

Imaginary part $\frac{dE}{dt}$:

- LO flux
- $\text{tail}^1 \sim \pi x^{3/2}$
- $\text{tail}^2 \sim x^3 \log(x)$
- $\text{tail}^3 \sim? \times x^{9/2}$

Other insertions possible:

- $M \rightarrow Q, L$

but do not contribute to leading $E$-logs: $\nu^2 x^{3n+1} \log^n x$ from $\text{tail}^{2n-1}$

Renormalization group enables to compute all leading logs: $E$-logs formula extends logs in $E(x)$ at $O(\nu)$ from self-force expanded up to 22 PN in Kavanagh-Ottewill-Wardell PRD 92 (2015)
Far UV divergences

Suppose one had the Far zone theory only: the UV divergence is not compensated by the NZ but it can be renormalized:

- drop the divergence (absorb it with a local counterterm)
- impose $\mu$–independence Goldberger, Ross, Rothstein PRD ’14

\[
\frac{dL_{\text{tail}}}{d \log \mu} = 0 \implies \frac{dM}{d \log \mu} = -\frac{2G^2 M}{5} \left( 2Q_{ij}^{(1)} Q^{(5)} - 2Q_{ij}^{(2)} Q^{(4)} + (Q_{ij}^{(3)})^2 \right)
\]

which can be solved by short-circuiting with analog equation for

\[
\frac{dQ_{ij}}{d \log \mu} = \frac{214}{105} (GM)^2 \ddot{Q}_{ij}(t, \mu)
\]

Goldberger, Ross PRD ’09
(see also Anderson+ ’82!)

Adding analogous formula for $J$ (Bernard, Blanchet, Faye, Marchand, Phys. Rev. D97 (2018)) and taking orbital average:

\[
M(\mu) = M(\mu_0) - MG^2 \sum_{n \geq 1} \frac{(2 \log(\mu/\mu_0))^n}{n!} \left( \beta_I G^2 M^2 \right)^{n-1} \langle Q_{ij}^{(n+2)} Q_{ij}^{(n+2)} \rangle
\]

\[
L(\mu) = L(\mu_0) - \frac{12MG^2}{5} \sum_{n \geq 1} \frac{(2 \log(\mu/\mu_0))^n}{n!} \left( \beta_I G^2 M^2 \right)^{n-1} \langle Q_{ij}^{(n+1)} Q_{ij}^{(n+2)} \rangle
\]
Not quite there for $E_{\text{circ}}$: need for $dE = \omega dL$

Using $Q_{ij}(M, \mu)$ one has (leading log part of) $M(M_0, \nu, \gamma)$, $L(L_0, \nu, \gamma)$, adding $dE = \omega dL$ one can compute $r(\nu)$ on circular orbits:

$\text{Energy}(r, \nu) \rightarrow E_{\text{circ}}(x)$ ($x \equiv (GM\omega)^{2/3}$)

\[
\gamma \equiv \frac{GM}{r} = x \left[ 1 + \frac{32\nu}{15} \sum_{n \geq 1} \frac{3n - 7}{n!} (4\beta_1)^{n-1} x^{3n+1} (\log x)^n \right]
\]

\[
E = -\frac{m\nu x}{2} \left[ 1 + \frac{64\nu}{15} \sum_{n \geq 1} \frac{6n + 1}{n!} (4\beta_1)^{n-1} x^{3n+1} (\log x)^n \right]
\]

\[
J = \frac{m^2 \nu}{\sqrt{x}} \left[ 1 - \frac{64\nu}{15} \sum_{n \geq 1} \frac{3n + 2}{n!} (4\beta_1)^{n-1} x^{3n+1} (\log x)^n \right]
\]

Remarkably $E(x)$ agrees 22PN order $x^{3n+1} (\log x)^n$ (up to $n = 7$), expanded self-force result by Kavanagh, Ottewill, Wardell, PRD (2015)
